DAY 02 · THEORY HANDOUT

Python Basics

Programs, the interpreter, and why Python is useful for data and AI.

Python tells a computer what to do

Three small ideas

- ✓ **Python** is a language for writing steps for a computer.
- ✓ A **program** is the list of steps you write.
- ✓ An **interpreter** is software that runs your Python steps.

Our first line

```
print("Hello, AI")
```

> **Why this line?** We can see if Python works. `print` shows text. The quotes mark the text to show.

1 · WRITE

Type the line

We write what we want in Python.

2 · RUN

Start Python

The interpreter runs the step we wrote.

3 · SEE

Read the result

The screen shows: Hello, AI

Why start AI work with Python?

LANGUAGE	GOOD FOR	WHY WE DO OR DO NOT START HERE
Python	Learning, data, and AI tests	Short, clear code and many ready tools for AI.
R	Numbers, charts, and study work	Good for data, but our AI lessons use more Python tools.
JavaScript	Web pages and web apps	We may use it when an AI tool needs a web page.
C++	Fast work close to the computer	Harder to read at first, but it runs much AI work behind Python.

Why Python? We can try an idea with a few clear lines. A **library** is a pack of ready code. Python has libraries for data, charts, and ML, so we can learn the idea before writing every part ourselves.

Why not only Python? Other languages help build fast parts and web apps. Python often gives them simple commands. Next, we will run Python and use data and chart libraries before simple ML.
